(54) Title: EXPRESSION OF MODIFIED ANTIBODIES IN AVIAN CELLS

(57) Abstract: The present invention relates to construct and methods which allow the expression of immunoglobulins or functional fragments thereof which have been altered so that they are humanised. The expression of the immunoglobulins or fragments thereof takes place in avian cells, and the constructs used have been altered such that the expression levels in avian cells are higher than what would have been expected by simply using a humanised construct. The alterations are based on changing codons so that each amino acid of the codon that is used is the one which is most often found in avians.

Concentrations of human IgG in culture medium from cells transiently transfected with 4ug p7.2

Concentration of chimaeric R24 minibody was determined by human IgG1 ELISA.

For % dilution, 0 = undiluted medium

1 Expression of modified antibodies in avian cells

2

3 The present invention relates to the expression of
4 immunoglobulins, or more specifically, antibodies which
5 have been altered so that the antibody is 'humanised', in
6 avian cells. The antibody expression may occur either in
7 vivo or in vitro. In the following document, the terms
8 immunoglobulin and antibody are used interchangeably.

9

10 Antibodies are proteins of the immunoglobulin class which
11 are produced on exposure to an antigen. The antibody
12 produced recognises that antigen, binding selectively to
13 it. There are five classes of immunoglobulin and the
14 following text relates primarily to antibodies of the
15 class IgG, although the other classes: IgA, IgD, IgY, IgE
16 and IgM are also included. An antibody molecule is made
17 up of two identical heavy chains linked by disulphide
18 bonds and two identical light chains. The biological
19 effector functions of an antibody molecule derive from
20 the properties of a constant region, which is identical
21 for antibodies of all specificities within a particular
22 class. It is the variable region that contains the
23 site/s which allows binding to a particular epitope and

1 there is a variable domain at the end of each of the
2 heavy and light chains. These variable domains are
3 followed by a number of constant domains. Thus, the
4 binding of an antibody to an antigen occurs through
5 interactions of the variable domains of each pair of
6 heavy and light chains. Specifically, binding occurs in
7 the areas of the variable regions where there is most
8 variability. These regions are known as hyper variable
9 regions or complementarity determining regions (CDRs).

10

11 Generally, with the exception of vaccinations, antibodies
12 are generated from a non-human source such as a mouse.
13 When used in human therapeutic applications, such
14 antibodies are usually recognised as foreign by the
15 immune system. This results in human anti-mouse
16 antibodies being produced, which may reduce the
17 therapeutic effect of the initial antibody or produce
18 undesirable side effects. Techniques have been developed
19 which allow the base of murine antibodies plus those of
20 other species to be manipulated in a way that the
21 original antigen specificity is retained, but all the
22 non-essential parts of the immunoglobulin sequence are
23 replaced with the equivalent human derived sequence.
24 This is known as 'humanising' an antibody. By using
25 humanised antibodies, immunogenic responses are largely
26 or highly avoided and effector functions improved.

27

28 However, even when an immunoglobulin sequence is
29 humanised there are still problems with the glycosylation
30 pattern of immunoglobulins for use in humans which have
31 not been produced in humans. IgG contains a conserved N-
32 glycosylation site located within the CH2 domain of each
33 heavy chain. The glycosylation pattern of

1 immunoglobulins is highly heterogeneous and has been
2 shown to have a significant effect on the biological,
3 pharmacological and physicochemical properties of the
4 immunoglobulin and include stability of the antibody and
5 half-life, tolerance in patient treatment and
6 interactions with complement components and other Ig
7 receptors. Alterations in the glycosylation pattern of
8 IgG has been linked to symptoms of rheumatoid arthritis.
9 The oligosaccharides are produced in the Golgi apparatus
10 of the cellular interior and is regulated largely by the
11 glycosyltransferases present in this organelle.
12 Currently, antibodies for therapeutic applications are
13 being produced in a variety of cell lines and
14 transgenically, but many of these systems are not
15 particularly suitable in terms of glycosylation. The
16 same antibody produced in different cell lines and
17 animals may therefore be afforded different
18 characteristics which may result in differing functions
19 and pharmacokinetics. The expression of
20 glycosyltransferases differs with different cell types,
21 with the result that the glycosylation pattern of the
22 protein produced differs from that produced by other cell
23 types. In particular, it has been noted that non-human
24 mammalian cell lines, for example hamster cell lines,
25 show markedly different glycosylation patterns to humans
26 and therefore are likely to cause problems with
27 immunogenicity. It is known that normal Chinese Hamster
28 Ovary (CHO) Cells, which are the standard used in the
29 industry for the manufacture of recombinant proteins, do
30 not express the enzyme N-acetylglucosaminyltransferase-
31 III (GlcNAcT-III), which has the role of synthesising
32 carbohydrates which contain GlcNAc (Campbell & Stanley,
33 1984). Since GlcNAc is expressed in human immunoglobulin

1 G, it is known that human proteins expressed in CHO cells
2 are not glycosylated in this manner. It is also
3 interesting to note that chicken IgG's also possess this
4 oligosaccharide. It has been found by experts in the
5 area, such as that reported by Raju et al. 2002, that the
6 glycosylation patterns of avian cells are far more
7 similar than non-human mammalian glycosylation patterns
8 to human glycosylation patterns. It therefore can be
9 seen that it would be highly advantageous to be able to
10 utilise chicken cells as a mode of production for
11 humanised recombinant proteins, compared to production of
12 such proteins in the standard mammalian cells.

13
14 US Patent No US5225539 entitled "Recombinant Altered
15 Antibodies and Method of Making Altered Antibodies"
16 describes a method of replacing the complementarity
17 determining regions of the heavy or light chain variable
18 domains of the receiving antibody with the corresponding
19 complementarity determining regions of a different
20 antibody with a different specificity. This method,
21 known as 'CDR grafting' is not the only method to produce
22 humanised antibodies, but is the most well known to those
23 knowledgeable in the field. The present invention
24 relates to antibodies which have been manipulated in any
25 manner which has the result of producing an antibody
26 which is more human-like in sequence than the wild-type
27 sequence.

28
29 However, although Patent No US5225539 describes a general
30 method which allows altered antibodies to be produced,
31 the methods described are directed towards production of
32 the altered antibodies in mammalian cells and does not
33 envisage the problems and advantages that arise when

1 producing antibodies in avian cells using this
2 technology.

3

4 While the methodology described in Winters' Patent
5 US5225539 is extremely useful for the production of CDR
6 grafted antibodies in mammalian cells, it can be seen
7 that it would also be useful to be able to easily produce
8 such CDR grafted and humanised antibodies in avian cells.
9 The production of such antibodies in avian cells would
10 have a significant advantage over the production in
11 mammalian cells if they are to be used as a human
12 therapeutic. This is because the glycosylation pattern
13 of human antibodies is more similar to avian antibodies
14 than the glycosylation of mammalian antibodies. As
15 previously mentioned, it is known that the glycosylation
16 pattern can have a significant effect on the bioactivity,
17 immunogenicity and therefore tolerance to the treatment
18 and also the pharmacokinetics of the antibody itself, and
19 therefore it would be extremely useful to produce
20 antibodies for human use of which the glycosylation
21 pattern is close to that of human antibodies.

22

23 It is also known that the yield of proteins produced in
24 non-avian transgenic animals, can be limited. It is
25 common practice to have to alter the culture conditions
26 or use expression vectors in order to obtain commercially
27 viable expression levels. The inventors have shown that
28 the expression of such proteins, especially
29 immunoglobulins and fragments thereof, in avian cells is
30 in general, higher than that observed in non-avian
31 animals. It can therefore be seen that it would be useful
32 and more time and cost-effective to produce antibodies
33 for human therapeutic use in avian cells. Figure 1 shows

1 the result of a Western blot to compare the expression
2 levels of the R24 protein in Chicken Hepatocellular (LMH)
3 cells, as compared to expression in Chinese Hamster Ovary
4 (CHO) cells. Figure 2 illustrates a comparison between
5 R24 protein produced in LMH and CHO cells, analysed by
6 human IgG1 ELISA. It can be seen that there is a
7 significantly higher level of protein produced in the LMH
8 cells as compared to the CHO cells. The inventors
9 believe that this is due to certain differences between
10 the translational machinery of the cell types in that the
11 LMH cells are more efficient in post-translationally
12 modifying the protein, than mammalian cells. This
13 belief is emphasised when the RNA message produced by
14 both cell types is analysed by PCR gel and the levels
15 produced by both types are similar.

16

17 One of the major problems of producing modified
18 antibodies in avian cells is that the codon usage in
19 avians differs from that in humans. Therefore, the
20 methodology described in US Patent No 5225539 is not
21 sufficient to allow the making of altered antibodies in
22 avian cells efficiently.

23

24 There is also the problem of actually producing that
25 which is coded for in a genetic construct in avian cells.
26 US Patent No US4816397 describes methods of producing
27 multi-chain polypeptides or proteins generally, however
28 again the methods are discussed mainly with regard to
29 mammalian cells and do not address the problems which
30 occur when producing multi-chain polypeptides, such as
31 antibodies, in avian cells. It should be noted that
32 there are a number of Patents and Patent Applications
33 which address the problem of producing basic single chain

1 proteins in avian cells, however in these cases they do
2 not refer to the production of complex multi-chain
3 polypeptides, such as antibodies, which pose their own
4 problems.

5

6 It can therefore be seen that it would be beneficial to
7 provide a method of producing and expressing modified
8 antibodies which have similar glycosylation patterns to
9 those naturally produced in humans or more similar than
10 the glycosylation patterns obtained from antibodies from
11 culture in mammalian cells.

12

13 It can also be seen that it would be beneficial to
14 provide a method of producing and expressing modified
15 antibodies in avian cells, as specifically producing and
16 expressing humanised antibodies in avian cells, so that
17 they can be used as human therapeutics.

18

19 It would also be extremely useful if the expression of
20 the modified antibodies could be specifically in the egg
21 of a genetically modified avian, so that the antibody can
22 easily be collected and purified.

23

24 It is therefore a first object of the present invention
25 to provide antibodies which have a glycosylation pattern
26 which is more similar to naturally occurring human
27 glycosylation patterns than those antibodies produced in
28 mammalian cells.

29

30 It is a further object of the present invention to
31 provide a method of expressing such humanised antibodies
32 in avian cells *in vitro* and *in vivo*.

33

1 It is a further object of the present invention to
2 provide a method of expressing humanised antibodies in
3 avian cells which are known to produce higher yields than
4 observed in non-avian cell systems.

5

6 It is a further object of the present invention to
7 provide a method of expressing humanised antibodies in
8 avian cells *in vitro* and *in vivo*.

9

10 It is a yet further object of the present invention to
11 provide antibodies for therapeutic use, which have
12 glycosylation patterns which are more similar to those
13 naturally occurring in humans, than the glycosylation
14 patterns observed in antibodies produced in mammalian
15 cells.

16

17 A still further object of the present invention is to
18 provide a construct which can be delivered into avian
19 cells, which will allow the production of antibodies or
20 humanised antibodies.

21

22 A final object of the present invention is to provide a
23 method of expressing humanised antibodies in avian cells,
24 so that they are specifically produced in the egg white
25 or egg yolk of an avian.

26

27 According to a first aspect of the present invention,
28 there is provided a DNA construct which when transfected
29 into an avian cell will allow the production of an
30 antibody molecule or functional fragment of said
31 molecule, and which comprises at least one sequence which
32 comprises the variable domain of an immunoglobulin heavy
33 chain and at least one sequence which comprises the

1 variable domain of an immunoglobulin light chain, and
2 wherein the DNA construct is based on a non-avian
3 sequence and one or more of the codons in the DNA
4 construct have been altered such that for the amino acid
5 being encoded, the codon used is that which most
6 frequently appears in avians.

7

8 Preferably, the construct also contains an avian signal
9 peptide sequence.

10

11 Preferably the construct is cloned into a viral vector
12 such as a lentivirus vector

13

14 Most preferably, the avian signal peptide sequence is a
15 signal peptide sequence from an egg white protein such as
16 lysozyme, ovalbumin, ovatransferrin or ovomucoid.

17

18 Most preferably, the construct also includes
19 immunoglobulin constant regions for dimerisation and
20 recruitment of effector functions.

21

22 Most preferably, the immunoglobulin constant regions are
23 CH2 and CH3 of any IgG class.

24

25 Still more preferably, the immunoglobulin constant
26 regions are human constant regions in order to provide a
27 humanised antibody.

28

29 Preferably, the construct may be transfected into an
30 avian cell using lipofection.

31

32 Alternatively, the construct is transfected into an avian
33 cell using electroporation.

1

2 A further option is that the construct may be directly
3 injected into the nucleus of an avian, into the germinal
4 disc of an oocyte.

5

6 Preferably, codon usage in the construct is maximised for
7 those codons most frequently appearing in avians. That
8 is, each codon is altered so that it still codes for the
9 same amino acid, but uses the codon most often found to
10 code for that amino acid in avians.

11

12 According to a second aspect of the present invention,
13 there is provided an avian cell, containing the construct
14 of the first aspect, which expresses an immunoglobulin
15 molecule or functional fragment of said molecule.

16

17 Preferably the expressed immunoglobulin molecule or
18 fragment thereof shows an avian glycosylation pattern.

19

20 Preferably the immunoglobulin or fragment thereof is
21 expressed at a higher expression level than a standard
22 human construct or humanised construct.

23

24 According to a third aspect of the present invention,
25 there is provided a method for producing avian cells
26 capable of expressing an immunoglobulin molecule or
27 functional fragment of said molecule, comprising
28 transfecting an avian cell with the DNA construct of the
29 first aspect.

30

31 Preferably the avian cell is a chicken cell, but may also
32 be duck, turkey, quail, or ostrich.

33

1 According to a fourth aspect of the present invention
2 there is provided an immunoglobulin or functional
3 fragment thereof produced using the method of the third
4 aspect.

5
6 According to a fifth aspect of the present invention
7 there is provided a transgenic avian, which expresses the
8 construct of the first aspect.

9
10 Preferably the antibody molecule, or functional fragment
11 of said molecule, that is coded for by the construct is
12 expressed in an egg of the transgenic avian.

13
14 Most preferably the construct is expressed in the egg
15 white.

16
17 Alternatively the construct is expressed in the egg yolk.

18
19 Preferably the immunoglobulin shows an avian
20 glycosylation pattern.

21
22 The present invention will now be illustrated, by way of
23 example only, with reference to the following Figures in
24 which:

25
26 Figure 1 shows a Western blot showing the differences in
27 protein expression between chicken and mammalian cells;
28 and

29
30 Figure 2. is a graph illustrating the differences between
31 protein expression levels in chicken and mammalian cells,
32 as analysed by ELISA; and

33

1 Figure 3 is a table giving the frequency of codon usage
2 in chickens.

3

4 And with reference to the following sequences in which;

5

6 SEQUENCE ID 1 is the sequence of human IgG Fc used for
7 construction of chimeric and humanised minibodies; and

8

9 SEQUENCE ID 2 is the sequence of the chickenised IgG Fc
10 DNA sequence.

11

12 SEQUENCE ID 3 is the nucleotide alignment of the
13 original and chickenised human IgG Fc.

14

15 SEQUENCE ID 4 is the amino acid alignment of original and
16 chickenised human IgG Fc.

17

18 SEQUENCE ID 5 shows the chickenised R24 nucleotide
19 sequence.

20

21 SEQUENCE ID 6 shows the complete chickenised nucleotide
22 sequence of the R24 chimeric minibody

23

24 Generating a Construct

25

26 In this example a construct is produced which allows a
27 humanised murine R24 antibody to be produced in chickens.

28

29 The DNA encoding the single chain variable fragment is
30 designed in *silico* so that it can then be directly
31 synthesised using standard methods.

32

33 The starting sequences are human Vh and Vl sequences

1 which may be obtained from human IgM antibody. Vh and Vl
2 complementarity determining regions (CDRs) of another
3 immunoglobulin (which in this case is the murine R24
4 immunoglobulin) are identified by standard methods (e.g.
5 see Antibodies-Structure and Sequence at
6 <http://www.bioinf.org.uk/abs>) and the R24 CDRs are
7 swapped directly into the human immunoglobulin framework.

8
9 The 3' end of the Vh DNA sequence is linked to the 5' end
10 of the Vl DNA sequence by a (Gly₄Ser)₃ peptide linker, as
11 seen in SEQUENCE ID 1. Included at the 3' end of the Vl
12 sequence is a sequence encoding a Bam HI restriction
13 site. This gives the humanised R24 sequence 1. An IgG1
14 leader sequence is linked to the 5' end of Vh with the
15 inclusion of an Eco RI restriction site.

16
17 To provide the constant region of the immunoglobulin 2,
18 human IgG1 CH2/CH3 (Fc) DNA is then cloned by RT-PCR from
19 RNA. The primers incorporate Bam HI and Sal I
20 restriction sites and can be seen in SEQUENCE ID 2. The
21 amplified DNA fragment is cloned directly following PCR
22 using the PCR cloning vector pGEM-T (Promega). E coli
23 DH5α cells are transformed with the ligated plasmid,
24 plated out on amp selection media and colonies screened
25 the following day by PCR with M13 vector primers.
26 Positive clones with the appropriately sized insert can
27 then be selected and plasmid DNA can be prepared and
28 inserts sequenced to confirm the presence of
29 immunoglobulin constant region DNA. The insert from one
30 positive DNA clone is removed by Bam HI/Sal I digestion
31 and ligated into pGEM 3Z (Promega), digested with the
32 same restriction enzymes. After transformation and
33 overnight growth on amp media, colonies are screened by

1 PCR with M13 vector primers and plasmid prepared from one
2 positive clone.

3

4 One μ g of the R24 gene synthesis product 1 is digested
5 with *EcoRI/BamHI* and ligated into plasmid hFc digested
6 with the same enzymes. After transformation and overnight
7 growth on amp media, colonies are screened by PCR with
8 M13 vector primers and plasmids prepared from clones with
9 the appropriately sized insert.

10

11 The entire insert DNA is then removed from pGEM3Z by
12 digestion with the restriction enzymes *EcoRI/SalI* and
13 ligated into the mammalian expression vector pCIneo
14 (Promega) digested with the same enzymes. After
15 transformation and overnight growth on amp media,
16 colonies are screened by restriction digestion
17 (*EcoRI/SalI*) of plasmid preparations. Plasmids may be
18 sequenced to confirm the presence of the minibody genes.

19

20 The insert can then be used to form a construct for
21 insertion into an avian cell. The insert, comprising the
22 Vh/Vl CDRs transplanted into a human immunoglobulin
23 framework 1 along with immunoglobulin constant domains 2
24 is removed from the pCIneo vector by *BglII/SfiI*
25 digestion. The fragment that is gained by this digestion
26 consists of;

27

28 a promoter/ enhancer 6,

29 an intron 4,

30 the minibody which comprises the R24 variable regions 1
31 and the CH2 and CH3 constant regions 2, and

32 a poly A tail 3

33

1 In order for the construct to be suitable for expression
2 in an avian cell, the immunoglobulin leader sequence is
3 exchanged for an avian specific sequence such as the
4 lysozyme signal peptide sequence 5. Also, both the R24
5 variable section coding sequence 1 and the CH2/CH3
6 constant region coding sequence 2 are chickenised.

7

8 'Chickenising' a Construct

9

10 Chickenising is defined as the alteration of codon usage
11 such that it is maximised for those codons most
12 frequently used in chickens. For expression in
13 transgenic chickens the codons of constructs are
14 optimised for most frequent codon usage in chickens.
15 However, it can be seen that the optimisation could be
16 for the most frequent codon usage of any avian species.

17

18 **EXAMPLE**

19 **Chickenising the human IgG Fc DNA sequence**

20 For expression in transgenic chickens the codons of the
21 chimaeric and humanised minibody versions of R24 are
22 optimised for most frequent codon usage in chickens
23 (*Gallus gallus*). A table detailing frequency of codon
24 usage was downloaded from <http://www.kazusa.or.jp> and is
25 reproduced in Figure 3.

26

27 For an example of how chickenisation is carried out, it
28 can be seen that the amino acid Valine is encoded by 4
29 different codons, GTG, GTA, GTT and GTC with GTG used
30 most frequently in chickens (46% GTG, 11% GTA, 19% GTT
31 and 23% GTC*). To chickenise the human IgG Fc DNA, all
32 valine codons were converted to GTG. Lysine is encoded
33 by two different codons, AAG and AAA, with AAG used most

1 frequently in chickens (58% vs 42%). All AAA codons in
2 the sequence were converted to AAG. Not all codons
3 required alteration. For example, the two codons for
4 aspartic acid, GAT and GAC are used with almost equally
5 (48% vs 52%) and are not changed during the
6 chickenisation.

7

8 Sequence ID 1 shows the codons for the original human IgG
9 Fc DNA sequence. Sequence ID 2 shows the chickenised
10 version of this. Sequence ID 3 shows an alignment of the
11 nucleotide sequences, a dot indicates a sequence match
12 and the missing dots show where the codons have been
13 altered. Sequence ID 4 is an alignment of the amino acid
14 sequences which show that despite the alterations to
15 various codons the amino acids are still 100% identical.
16 Sequence ID 5 and 6 show the chickenised R24 scFv
17 sequence and complete chickenised R24 minibody
18 respectively.

19

20 * figures as given in Figure 3 = 99%

21

22 Inserting the Construct into an avian Cell

23

24 There are a number of possible methods that can be used
25 for transfection of an avian cell with the construct.
26 Transfection can either be transient or stable.

27

28 In transient transfection, supercoiled plasmid containing
29 the gene of interest is introduced into the nucleus of
30 the target cells at high copy number for short periods of
31 time (usually 24-96 hrs). During transient transfections
32 the DNA does not integrate into the cellular chromosomes.

33

1 For stable transfection either linear or plasmid DNA can
2 be introduced into the target cells and will either
3 integrate into the chromosomes or be maintained as a
4 stable episome. Linear DNA is optimal for stable
5 integration but is taken up less efficiently than
6 supercoiled plasmid. Cells in which the DNA has
7 integrated or is maintained as a stable episome can be
8 distinguished by selectable markers. For transfections
9 with pCIneo, the plasmid carries the neomycin
10 phosphotransferase gene which confers resistance to
11 aminoglycosides such as G418. Culturing cells in the
12 presence of G418 selects for those that carry the
13 integrated or episomal DNA.

14
15 A variety of methods are available for the introduction
16 of DNA into mammalian cells and these include calcium
17 phosphate coprecipitation (Graham, R.L. and van der Erb,
18 AJA (1973) Virology 52, 456.) and electroporation
19 (Andreason, G.L. and Evans, G.A. (1988) BioTechniques 6,
20 650; Shigikawa, K. and Dover, W.J., (1988) BioTechniques
21 6, 742) but these have largely been superseded by
22 cationic liposome-mediated transfection (Felgner, J. et
23 al (1993) J Tiss Cult Metho. 15, 63). Other compounds
24 known to mediate transfection of mammalian cells include
25 lipopolyamines (Remy, J-S, Sirlin, C., Vierling, P and
26 Behr, J-P. (1994) Bioconjugate Chem. 5, 647) and
27 dendrimers (Haensler, J. and Szoka, FC (Jr) (1993)
28 Bioconjugate Chem 4, 372.).

29

30 Cationic liposomes, lipopolyamines and dendrimers coat the
31 DNA to be transfected and mediate its passage through the
32 cell membrane. A variety of factors influence the
33 efficiency of transfection and these include cell type,

1 media type and presence of serum and antibiotics, amount
2 and quality of plasmid DNA and cytotoxicity of
3 transfection reagent. All of these usually have to be
4 optimised for each cell type and plasmid construct.

5

6 Alternatively, zygotic injection of the construct could
7 also be used to incorporate the construct.

8

9 Alternatively the construct may be cloned into a viral
10 vector such as a lentivirus vector and such vectors are
11 commercially available. Lentiviruses as vectors have been
12 developed from slow retroviruses, such as equine
13 infectious anaemia virus (EIAV), feline immunodeficiency
14 virus (FIV) or Human Immunodeficiency Virus (HIV). The
15 significant advantage using a lentiviral vector is that
16 the virus will infect cells that are not dividing, which
17 is appropriate to certain cell types of the present
18 invention.

19

20 If the construct contains a promoter such as an egg white
21 protein signal peptide, transgenic avians can then be
22 produced which lay eggs with the antibody of interest in
23 the egg white.

24

25 The chickenised construct may also be designed for
26 insertion into a gene contained within a plasmid, for
27 example it may be designed for insertion into a lysozyme
28 gene contained within a plasmid. The ATG site on the
29 lysozyme gene in the plasmid is destroyed by creating a
30 SalI site so that the lysozyme protein is not expressed.
31 The chickenised construct, which has its own ATG can then
32 be cloned into the SalI site.

33

1 Various modifications may be made to the invention herein
2 described, without departing from the scope thereof. For
3 example, any appropriate immunoglobulin sequence may be
4 used and any appropriate avian species may be used in
5 place of chickens with the codon bias changing
6 appropriately.

1 CLAIMS

2

3

4 1. A DNA construct which when transfected into an avian
5 cell will allow the production of an antibody
6 molecule or functional fragment of said molecule,
7 and which comprises at least one sequence comprising
8 the variable domain of an immunoglobulin heavy chain
9 and at least one sequence comprising the variable
10 domain of an immunoglobulin light chain, and wherein
11 the DNA construct is based on a non-avian sequence
12 and one or more of the codons in the DNA construct
13 have been altered such that for the amino acid being
14 encoded, the codon used is that which most
15 frequently appears in avians.

16

17 2. A DNA construct as claimed in Claim 1, wherein the
18 construct also contains an avian signal peptide
19 sequence.

20

21 3. A construct as claimed in the previous Claims,
22 wherein the construct is cloned into a viral vector.

23

24 4. A construct as described in Claim 3, wherein the
25 viral vector is a lentivirus vector.

26

27 5. A DNA construct as claimed in Claims 2 to 4, wherein
28 the avian signal peptide sequence is a signal
29 peptide sequence from an egg white protein.

30

31 6. A DNA construct as described in Claim 5, wherein the
32 egg white protein is chosen from the list lysozyme,
33 ovalbumin, ovatransferrin or ovomucoid.

34

- 1 7. A DNA construct as claimed in any of the previous
2 Claims, wherein the construct also includes
3 immunoglobulin constant regions for dimerisation and
4 recruitment of effector functions.
5
- 6 8. A DNA construct as claimed in Claim 7, wherein the
7 immunoglobulin constant regions are CH2 and CH3.
8
- 9 9. A DNA construct as claimed in Claims 7 or 8, wherein
10 the immunoglobulin constant regions are human
11 constant regions.
12
- 13 10. A DNA construct as described in any of the previous
14 Claims, wherein the construct may be transfected
15 into an avian cell using electroporation.
16
- 17 11. A DNA construct as claimed in Claims 1 to 9, wherein
18 the construct may be transfected into an avian cell
19 using lipofection.
20
- 21 12. A DNA construct as claimed in Claim 1 to 9, wherein
22 the construct may be directly injected into the
23 nucleus of an avian.
24
- 25 13. A DNA construct as claimed in Claim 12, wherein the
26 construct may be directly injected into the germinal
27 disc of an oocyte.
28
- 29 14. A DNA construct as described in any of the previous
30 Claims, wherein codon usage in the construct is
31 maximised for those codons most frequently appearing
32 in avians.
33

- 1 15. An avian cell containing the construct described in
2 Claims 1 to 15, which expresses an immunoglobulin
3 molecule or functional fragment of said molecule.
4
- 5 16. An avian cell as described in Claim 16, wherein the
6 expressed immunoglobulin molecule or functional
7 fragment thereof shows an avian glycosylation
8 pattern.
9
- 10 17. An avian cell as described in Claims 16 or 17,
11 wherein the immunoglobulin or fragment thereof is
12 expressed at a higher expression level than a
13 standard human construct or humanised construct.
14
- 15 18. A method for producing avian cells capable of
16 expressing an immunoglobulin molecule or functional
17 fragment of said molecule, comprising transfecting
18 an avian cell with the DNA construct as described in
19 Claims 1 to 15.
20
- 21 19. Preferably the avian cell is selected from a list of
22 chicken cell, duck cell, turkey cell, quail cell or
23 ostrich cell.
24
- 25 20. An immunoglobulin or functional fragment thereof
26 which is produced using the method described in
27 Claims 19 and 20.
28
- 29 21. A transgenic avian which expresses the construct
30 described in Claims 1 to 15.
31

- 1 22. A transgenic avian as described in Claim 22, wherein
2 the molecule coded for by the construct is expressed
3 in the egg of the transgenic avian..
4
- 5 23. A transgenic avian as claimed in Claim 23, wherein
6 the construct is expressed in the egg white.
7
- 8 24. A transgenic avian as described in Claim 23, wherein
9 the construct is expressed in the egg yolk.
10
- 11 25. A transgenic avian as described in Claims 22 to 25,
12 wherein the expressed immunoglobulin shows an avian
13 glycosylation pattern.

1/5

Figure 1: Equal numbers of cells were transfected with increasing amounts of chickenised R24 in pCIneo. Expression was detected by Western blotting using anti-human IgG Fc

2/5

Figure 2: Concentrations of human IgG in culture medium from cells transiently transfected with 4ug p7.2
Concentration of chimaeric R24 minibody was determined by human IgG1 ELISA.
For % dilution, 0 = undiluted medium
